

Poisson distribution

A stochastic experiment is repeated many times. Let the expected number of successes be λ . Then the probability of observing n successes would be

$$P_{\lambda}(n) = \frac{\lambda^n e^{-\lambda}}{n!}$$

The Poisson distribution is of interest especially for TCSPC: The expected number of photons in any TCSPC channel is given by the 'real' decay (including convolution with the IRF etc.), while the stochastic nature of the measurement process (either a photon is detected or it is not) introduces noise, which follows a Poisson distribution. In the limit of large λ the Poisson distribution approaches a Gaussian distribution with a width of $\sqrt{\lambda}$ centred around λ .

In the Gaussian limit [least squares fitting](#) may be applied, otherwise [MLE fitting](#) is preferable.
